

# FRTB

## Three Quantitative Curiosities

**Disclaimer**. The views stated in this presentation are personal views of the author and **do not necessarily reflect the official views of NAB**

## FRTB - what we want to discuss

- VaR vs ES (Expected Shortfall) – is it really necessary?
- Liquidity Horizons and Overlapping Observations – are there unintended consequences?
- Mixing Correlation Matrices – is it legitimate?
- Some results from QIS

## VaR vs ES

### Common Steps:

1. Generate the vector of market perturbations :  
 $\Delta R = (\Delta R_1, \Delta R_2, \dots, \Delta R_n)$  and apply then to the current market rate vector  $R = (R_1, R_2, \dots, R_n)$  to generate the perturbed vector  $\tilde{R} = R + \Delta R$ . Perturbations can also be fractional or mixed, Perturbations can be generated by a Monte Carlo simulation or sampled from historical data.

2. For portfolio  $P$  generate a vector of hypothetical P&Ls:

$$\Delta P(R) = P(\tilde{R}) - P(R) = (\Delta P_1, \Delta P_2, \dots, \Delta P_n)$$

3.  $VaR_q(P)$   $ES_q(P)$   
 $= -Quantile_{1-q}(\Delta P(R))$   $= -E(\Delta P(R) | \Delta P(R) < -VaR_q(P))$

$$q=99\%$$

$$q=97.5\%$$

## VaR vs ES

VaR has been in use since the 90s

Academics have been pushing for ES because:

A. It is coherent:  $ES(P_1 \cup P_2) \leq ES(P_1) + ES(P_2)$

B. It catches outliers.

C. It potentially takes autocorrelations in the data in to account

~~~~~

A. VaR is not coherent, but known examples are based on discontinuous P&L vectors. In practice portfolios are well diversified and continuous

B. For a typical 97.5% level and >500 simulation you have 12 observation in the tail, so the impact of the outlier is largely diluted.

Also, VaR is just one risk metrics, Stress Test is designed to catch portfolio non-linearities.

VaR is easier for management and traders to understand

C. We'll have a look this later.

## VaR vs ES – some examples

In terms of the order statistics:

$$VaR(\Delta P(R))_q = -\Delta P(R)_{[(1-q)n]}; \quad ES(\Delta P(R))_q = -\frac{1}{[(1-q)n]} \sum_{i=1}^{[(1-q)n]} \Delta P(R)_{[i]}$$

As per Basel recommended levels we compare 99% VaR vs 97.5% ES

| Distribution | VaR(99%) | ES (97.5%) | Ratio |
|--------------|----------|------------|-------|
| Normal       | -2.341   | -2.330     | 0.996 |
| t(7)         | -2.967   | -3.002     | 1.012 |
| t(3)         | -4.503   | -4.806     | 1.067 |
| t(2)         | -7.386   | -8.406     | 1.14  |
| Cauchy       | -33.120  | -71.572    | 2.161 |

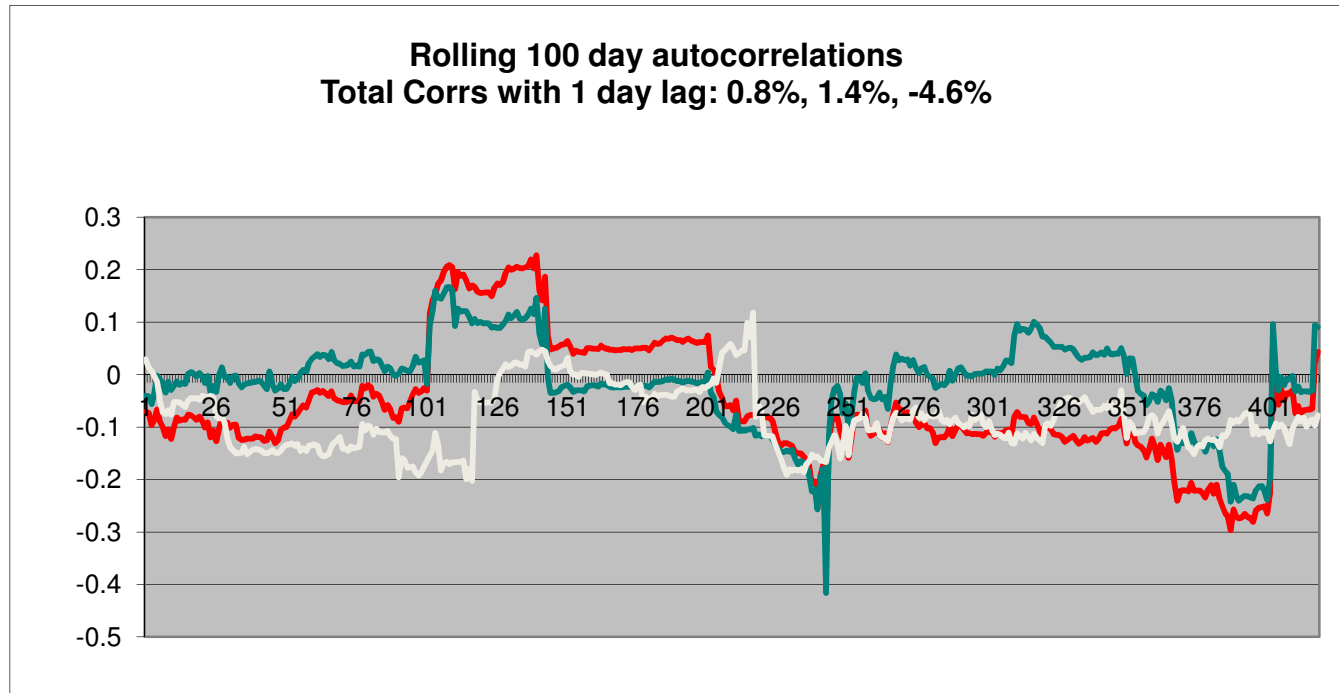

## VaR vs ES – more examples.

### My point is: What's the point?

| Trade | Var (99%)/ ES (97.5%) Ratio | SVaR (99%)/ SES (97.5%) Ratio |
|-------|-----------------------------|-------------------------------|
| 1     | 0.949                       | 0.989                         |
| 2     | 0.983                       | 0.987                         |
| 3     | 0.967                       | 1.018                         |
| 4     | 0.956                       | 1.035                         |
| 5     | 0.981                       | 1.050                         |
| 6     | 0.956                       | 1.000                         |
| 7     | 1.000                       | 0.985                         |
| 8     | 0.977                       | 1.022                         |
| 9     | 0.977                       | 0.965                         |
| 10    | 1.014                       | 0.997                         |

## VaR vs ES - Data Autocorrelation

P&L data typically does not have significant autocorrelation

For longer lags correlation may increase

As we'll see later, modelled ES/VaR ratio does not change if autocorrelation is introduced

## Liquidity Horizons

### Motivation:

Time required to unwind the position - .

### Current liquidity horizon:

10 (working) days for all asset classes.

### Proposed liquidity horizons:

10, 20, 60, 120, 250 days depending on the asset class

### Problem:

The sample is not long enough to generate IID of the required length. Even if it was, the question of 'The Second I' - *Identical* would arise

### Two solutions:

- Use overlapping sums
- Use scaling by  $\sqrt{LH}$ , implicitly assuming the IID and normality of the perturbations.

## Liquidity Horizons

### Mathematically

Let  $X = (x_1, x_2, \dots, x_n)$ , define  $Y = (y_1, y_2, \dots, y_{n-m})$  where

$$y_i = \sum_{j=i}^{i+m-1} x_j \quad \text{and } m \text{ is the liquidity horizon}$$

Then calculate VaR and ES on  $Y$  as usual

Some mathematics is possible, but we do mathematical experimentation using Monte Carlo

## Mixing Correlation Matrices

This is an excerpt from the Basel consultative document :

98. The discounted net cash flows at each vertex are then put into the following formula, which recognises offsetting between cash flows at different vertices in the same currency:

$$K_b = \sqrt{\sum_i RW_i^2 MV_i^2 + \sum_i \sum_{j \neq i} \rho_{ij} RW_i MV_i W_j MV_j} = \sqrt{VRV}$$

Where  $MV_i$  is the present value of the net cash flow at vertex  $i$ ,  $RW_i$  is the risk weight assigned to vertex  $i$ , and  $\rho_{ij}$  is the correlation parameter between vertices  $i$  and  $j$ ,  $V = RW \times MV$ ,  $R$  - correlation matrix

99. The first correlation matrix below should be used for  $\rho_{ij}$  if the net cash flows at vertices  $i$  and  $j$  have the same sign (long/long or short/short). The second correlation matrix below should be used if the net cash flows at vertices  $i$  and  $j$  have different signs (long/short).

*This approach (Cashflow based) is now abandoned in favour of the Sensitivity Based Approach*

## Mixing Correlation Matrices
